

Mentor class 03 - JavaScript

You have 5 exercises that combine 1 application. Divide the work between all of you, or work together on each of them.

1. Exercise I:

- You are given an array (in the starter-files) of activities that fill out one workday.
- Iterate through that array, create a table (once), and for every iteration create how many rows for that table you need.

**** Use `document.createElement` for each of the elements (it's a must).**

- Fill out the content of the table columns.

**** Make all of the tasks above dynamically through javascript. (if it wasn't obvious)**

2. Exercise II:

- Based on the hours in each of the activities, calculate how much percentage of the day they take.
- Create an extra cell in the table-head for the Percentage heading.
- Create an extra cell in each row in the table-body and fill it out with the percentage for each of the activities.
- Now that you've added it to the html, add it to each of the activities in the initial array that was given as a 3rd (second index in js) element.

3. Exercise III:

- Remove the activity with an index 2 from the activities array (use an array method to achieve this)
- Now that you've removed the activity from the array, remove it from the html as well. (or maybe re-create the table-body from scratch without

that activity?)

4. Exercise IV:

- You may have already noticed that some of the code, like creating each row, is repeating 3 times. Once, for the headings of the table in the table-head. Twice, to create each of the rows in the table-body. The third time, to create the table-body from scratch in *Exercise III*.
- Make a function **createRow** which will **return** a fully populated **row**. Use function attributes/parameters to fill out the text of the different columns each time you need to create a different row.
- Use that function to create 3 different rows and append the rows wherever needed.

5. Exercise V:

- When you re-create the table-body from scratch in *Exercise III*, you are re-writing a for-loop for a second time, like you did the first time when there was no percentage column.
- Create a function **populateBody** which will have the for-loop inside (so you don't have to write it twice), creates a row using the **createRow** function (yes, you are allowed to call functions into other function), and appends the newly created row to the table-body.

Notes

1. Write the exercises in the same files that are sent and **do not create separate files** for every exercise, because it is one application after all.
 2. Place the challenge in a GitLab project named ****mentor-classes-group-number**** (example: mentor-classes-group-1, that you already created).
- Each challenge every week will be in a separate branch (DO NOT WORK ON MASTER).

Good luck!
